Should we learn the misfit distribution?

Goal: Estimating spatially dependent probability distributions

Figure: pdf (red curve) versus collected data (histogram)

- For various shapes or modalities
- Samples heterogeneously scattered across space + no replications.
- Uncertainty Quantification.

What is the SLGP ?

$$\begin{cases} (Z_{x,y})_{x \in D, y \in \mathcal{T}} \sim \mathcal{GP} \\ W_{x,y} := \frac{e^{Z_{x,y}}}{\int_{\mathcal{T}} e^{Z_{x,u}} du} \sim \mathcal{SLGP} \end{cases}$$

Gautier, Athénaïs and David Ginsbourger (2021). *Continuous logistic Gaussian random measure fields for spatial distributional modelling*. arXiv: 2110.02876 [math.ST].

- Random measure at each $x \rightarrow$ Random field of measures.
- Distribution characterized by $Z_{x,y} - Z_{x,y'} = \log W_{x,y} - \log W_{x,y'}$ ($x \in D, y, y' \in \mathcal{T}$).

Spatial regularity of the SLGP

Spatial regularity of the SLGP

For W a SLGP, if it satisfies for all $(x, x') \in D^2, (y, y') \in \mathcal{T}^2$:

$$\text{Var} [\log W_{x,y} - \log W_{x',y'}] \leq C \cdot \max(\|x - x'\|_\infty^{\alpha_1}, \|y - y'\|_\infty^{\alpha_2}) \quad (1)$$

for constants $C, \alpha_1, \alpha_2 > 0$, then for all $\gamma > 0, \delta > 0$, there exists a constant $K_{\gamma,\delta}$ such that for all $x, x' \in D^2$

$$\begin{aligned} \mathbb{E} [d_H(W_{x,\cdot}, W_{x',\cdot})^\gamma] &\leq K_{\gamma,\delta} \|x - x'\|_\infty^{\gamma\alpha_1/2-\delta} \\ \mathbb{E} [KL(W_{x,\cdot}, W_{x',\cdot})^\gamma] &\leq K_{\gamma,\delta} \|x - x'\|_\infty^{\gamma\alpha_1-\delta} \\ \mathbb{E} [d_{TV}(W_{x,\cdot}, W_{x',\cdot})^\gamma] &\leq K_{\gamma,\delta} \|x - x'\|_\infty^{\gamma\alpha_1-\delta} \end{aligned} \quad (2)$$

where d_H is the Hellinger distance, KL the Kulback-Leibler divergence, d_{TV} the total variation distance.

Result adapted from:

Pati, Debdeep, David B Dunson, and Surya T Tokdar (2013a). “Posterior consistency in conditional distribution estimation”. In: *Journal of multivariate analysis* 116, pp. 456–472.

Posterior consistency

If the model is well-specified, then we achieve posterior consistency.

Important aspects of the implementation

$$\begin{cases} (Z_{x,y})_{x \in D, y \in \mathcal{T}} \sim \mathcal{GP} \\ W_{x,y} := \frac{e^{Z_{x,y}}}{\int_{\mathcal{T}} e^{Z_{x,u}} du} \sim \mathcal{SLGP} \end{cases}$$

We focus on *finite-rank* GPs $Z_{x,y} = \sum_{j=1}^P f_j(x, y) \varepsilon_j$

Considered functions

In the upcoming R package:

- Multivariate discrete Fourier Features
- Random Fourier Features
- Space-filling Random Fourier Features
- Inducing points
- User-defined functions (!)

Conditioning on data

Conditioning on data

For locations $(x_i)_i \in D^n$, observations $(y_i)_{i=1}^n \in \mathcal{T}^n$ and a finite rank SLGP, assuming independent Y_i 's we have the posterior:

$$\pi(\varepsilon | \mathcal{T}_n) \propto \pi(\varepsilon) \prod_{i=1}^n \frac{e^{\sum_{j=1}^p f_j(x_i, y_i) \varepsilon_j}}{\int_{\mathcal{T}} e^{\sum_{j=1}^p f_j(x_i, u) \varepsilon_j} du} \quad (3)$$

This posterior is **log-concave**.

- Fast optimization (MAP)
- fast MCMC sampling.¹

¹Dwivedi et al. 2018.

SLGP: pros and cons.

The SLGP:
$$\frac{e^{Z_{x,y}}}{\int_{\mathcal{T}} e^{Z_{x,u}} du}$$

Pros:

- Flexible model, non parametric
- Can be conditioned on data (with little to no replications)
- Bayesian: probabilistic response (UQ + sequential)
- Encoding prior knowledge in the GP

Cons:

- Computationally expensive

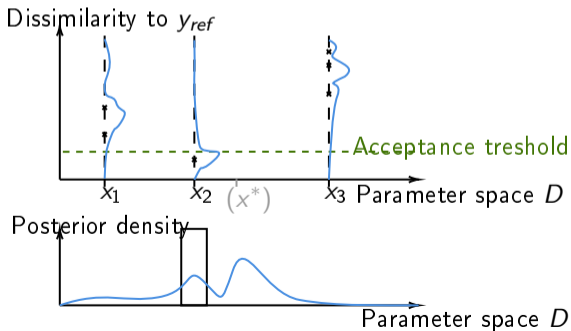

- 1 Motivation: Stochastic inverse problems and Approximate Bayesian Computations
- 2 Learning probability distribution fields with the SLGP
 - Our building-brick: the Logistic Gaussian Process
 - Spatial Logistic Gaussian Process
 - What can we say about the SLGP, with maths ?
 - Implementation
- 3 Enabling statistical inference, and hydrogeological application.
 - The framework of SLGP-ABC
 - Applying SLGP-ABC in hydrogeology (random design)
- 4 Sequential design: how to guide data acquisition
 - Targeted sampling in inverse problems
 - Applying sequential SLGP-ABC in hydrogeology

Idea presented in:

Gautier, Athénaïs, David Ginsbourger, and Guillaume Pirot (2020). “Probabilistic ABC with Spatial Logistic Gaussian Process modelling”. In: *NeurIPS 2020. Third Workshop on Machine Learning and the Physical Sciences*.

Models directly the misfit distribution:

Idea presented in:

Gautier, Athénaïs, David Ginsbourger, and Guillaume Pirot (2020). "Probabilistic ABC with Spatial Logistic Gaussian Process modelling". In: *NeurIPS 2020. Third Workshop on Machine Learning and the Physical Sciences*.

Main elements about SLGP-ABC

- Works in low data regime.
- Little assumption on the misfit likelihood.
- Can use any data-set and any prior on x .
- Posterior consistency for the ABC-posterior.

An hydrogeological application: setup

- Contaminant released at depth x (0 to 10m.), aquifer with unknown structure
- We observe a contaminant plume and want to recover x .²

Figure: Flow through the aquifer [left panel, **not observed**], contaminant concentration at 100 boreholes [right panel, **observed**]

An hydrogeology application: simulations

New simulations and computed misfits at a source depth x .

(a) $x = 4.90\text{m}$, misfit ≈ 0.035

(c) $x = 7.96\text{m}$, misfit ≈ 0.63

(b) $x = 4.90\text{m}$, misfit ≈ 0.35

(d) $x = 7.96\text{m}$, misfit ≈ 0.22

Sequential

Criteria used

Application

Minimize the “future uncertainty” for adding k simulations at x^* :

- **Random posterior at x**

$$\hat{\pi}_{SLGP-ABC}(x)$$

Two criteria used

Minimize the “future uncertainty” for adding k simulations at x^* :

■ **Variance**

$$\text{Var}_{\text{SLGP}|\mathcal{D}_{1:n}\text{UD}^*}(\hat{\pi}_{\text{SLGP-ABC}}(x))$$

■ **Median Interquartile Range**

$$\text{IQR}_{\text{SLGP}|\mathcal{D}_{1:n}\text{UD}^*}(\hat{\pi}_{\text{SLGP-ABC}}(x))$$

where IQR is the inter-quartile range.

Two criteria used

Minimize the “future uncertainty” for adding k simulations at x^* :

- **Integrated Variance**

$$\int_x \text{Var}_{\text{SLGP}|\mathcal{D}_{1:n}\text{UD}^*} (\hat{\pi}_{\text{SLGP-ABC}}(x)) dx$$

- **Integrated Median Interquartile Range**

$$\int_x \text{IQR}_{\text{SLGP}|\mathcal{D}_{1:n}\text{UD}^*} (\hat{\pi}_{\text{SLGP-ABC}}(x)) dx$$

where IQR is the inter-quartile range.

Two criteria used

Minimize the “future uncertainty” for adding k simulations at x^* :

■ **Expected Integrated Variance (EIV)**

$$L_{EIV}(x^*) := \mathbb{E}_{y^*|x^*} \left[\int_x \text{Var}_{\text{SLGP}|\mathcal{D}_{1:n}\cup\mathcal{D}^*} (\hat{\pi}_{\text{SLGP-ABC}}(x)) dx \right]$$

■ **Integrated Median Interquartile Range (IMIQR)**

$$L_{IMIQR}(x^*) := \mathbb{E}_{y^*|x^*} \left[\int_x \text{IQR}_{\text{SLGP}|\mathcal{D}_{1:n}\cup\mathcal{D}^*} (\hat{\pi}_{\text{SLGP-ABC}}(x)) dx \right]$$

where IQR is the inter-quartile range.

Conclusion and upcoming work

What we saw:

- Leverage random fields for density field estimation
- Application to inverse problems: accelerate inference in low data regime
- Application to inverse problems: guide data acquisition

Perspectives and related works:

- Continuing implementation and package release
- Evaluating predictions (look into probabilistic forecasting for scoring of fields of density)
- Benchmark the approach (compare to other estimation methods, use other test cases)

Thank you for your attention!

Using simulations to compute the criterions

Data: x^* , $k \geq 1$, $\mathcal{D}_{1:n}$, $(\varepsilon^{(i)})_{1 \leq i \leq M}$, n_{sim}

Result: $\hat{L}(x^*)$

Use $\sum_{i=1}^M \frac{1}{M} \varepsilon^{(i)}$ as approx. of $\pi[\varepsilon | \mathcal{D}_{1:n}]$;

for $i \leftarrow 1$ **to** n_{sim} **do**

Generate k new observations at x^* from the current mean field: y_1^*, \dots, y_k^* ;

Reweight the $\varepsilon^{(i)}$: $\omega_i \propto \prod_{j=1}^k \frac{e^{\sum_{j=1}^p f_j(x^*, y_j^*) \varepsilon_j}}{\int_{\mathcal{T}} e^{\sum_{j=1}^p f_j(x^*, u) \varepsilon_j} du}$;

Use $\sum_{i=1}^M \omega_i \varepsilon^{(i)}$ as approx. of $\pi[\varepsilon | \mathcal{D}_{1:n} \cup \mathcal{D}^*]$;

Compute and store the criterion of interest;

end

Average the stored values of the criterion.

Proper scoring rule for (random) pdf

Positively oriented **proper scoring rule**, inspired from probabilistic forecasting:

Steinwart, Ingo and Johanna F Ziegel (2021). "Strictly proper kernel scores and characteristic kernels on compact spaces". In: *Applied and Computational Harmonic Analysis* 51, pp. 510–542.

Compare random distribution Π (SLGP-ABC posterior) to the reference p_0 (true source):

$$S(\Pi, p_0) := -\mathbb{E}_{P \sim \Pi} [\gamma(P, p_0)] + \frac{1}{2} \mathbb{E}_{P, P' \sim \Pi} [\gamma(P, P')] \quad (4)$$

where $\gamma(P, P') := \mathbb{E} [(X - X')^2] + \mathbb{E}' [(Y - Y')^2] - 2\mathbb{E} [(X - Y)^2]$ with $X, X' \sim P$ and $Y, Y' \sim P'$.

Scoring (random) densities

Is adaptive SLGP-ABC better than random-ABC ? Using a (positively oriented)
proper scoring rule:
